Personal

Born on October 2, 1984
Indonesian citizen

Research Interests

Macroeconomics, especially the distribution; development economics; monetary economics

Education

PhD Candidate in Economics, Research School of Economics, The Australian National University, 2021 – 2024 (expected)
M.Ec. (Economics), Research School of Economics, The Australian National University, 2016
BSc. in Mathematics, Mathematics Department, Bandung Institute of Technology (ITB), Indonesia, 2006

Employments

Economist on Central Bank of Indonesia, February 2017 - Present
Doctoral Student Associate in Centre for Applied Macroeconomic Analysis (CAMA), The Australian National University, Australia, February 2016 – December 2019
Teaching assistant, The Australian National University, February 2016 – July 2016
Researcher on Central Bank of Indonesia, April 2010 – January 2017
Analyst on Automotive Finance Company, August 2006 – March 2010
Teaching assistant, Bandung Institute of Technology, August 2004-2006

Working Papers

Monetary and Macroprudential Policy Mix under Financial Frictions Mechanism with DSGE Model.

Abstract:

In this research a DSGE model is developed for the small open economy of Indonesia, complemented with the inclusion of financial frictions in the form of collateral constraints amongst households and a financial accelerator amongst entrepreneurs. Inclusion of the banking sector in the model enables analysis of the policies required to mitigate shocks originating in the banking sector or indeed other shocks as well as their influence on financial intermediaries in the form of banks in the economy.

The model demonstrates that shocks in the banking sector, for instance raising the CAR requirement, impacts the real sector through the credit channel, which undermines GDP and lowers the rate of inflation. The financial accelerator mechanism in the model evidence procyclicality in the financial system to economic conditions. An economic contraction elicits a response from the banking industry to reduce the amount of credit allocated, which is the root of the risk faced by the banks. In the face of rising ex-post idiosyncratic shocks, exceeding those ex-antes, indicates that bank assessments of expected return on capital of an entrepreneur are larger than the actual realization, forcing banks to bear the risk. Such conditions further encourage banks to reduce credit disbursement to avoid eroding bank capital.

The simulations also show that a policy mix of monetary and macroprudential policy not only achieves sustainable GDP and stable inflation but also helps to control consumption, thereby reducing demand for imported goods. Coupled with stable exports, a slowdown in imports will have a favorable effect on the current account.

Interbank Market with DSGE Model.

Abstract:

In this study, the DSGE model was built for Indonesia's small open economy which has been equipped with an interbank market mechanism to describe financial frictions from the supply side of banks where there is a portfolio optimization mechanism by banks between channeling credit or saving in risk free assets, while financial friction on the demand side is modeled with collateral constraints and financial accelerators.

The simulation results show that the shock that occurs in the interbank market will affect the condition of banks in general, especially in bank capital, CAR, and loan to deposit ratio (LDR). The condition of the bank's balance sheet will affect the real sector. This model is also able to capture procyclicality and financial accelerators that occur due to financial frictions in the economy, where GDP will be higher during the expansion phase compared to conditions without financial frictions, and vice versa, where GDP will be lower during the contraction phase. The contraction in the economy will be responded by banks by reducing the level of lending, due to the high risk faced by banks, which will also increase bank lending rates so that entrepreneurs find it increasingly difficult to receive loans. This condition makes the Bank increasingly put pressure on lending to prevent the erosion of the Bank's capital.

The simulation results also show that a shock in the form of a policy mix of monetary and macroprudential policies will suppress credit growth more deeply, compared to conditions without macroprudential

policies. GDP and inflation decreased but did not change too much compared to conditions using only the BI rate policy. In the use of the policy mix, the decline in consumption is offset by a decrease in imports, so that GDP tends to be stable. The policy mixes also resulted in stable inflation.

Balance of Payment Indonesia Model.

Abstract:

In this study, the Balance of Payments Indonesia Model for Assessments has been built with a simultaneous equation approach and uses the two-step Error Correction Model (ECM) econometric method to estimate all equations. The components that are modeled are also more detailed, especially for the current account block so that it is expected to make it easier for model users in storytelling.

The simulation results show that the model is in line with the existing economic theory. The forecast error of the model is also relatively small, especially for the components in the current account section. Simultaneous equations in the model make it possible to see the impact of changes in current accounts and financial accounts on other macroeconomic variables.

Although the model involves many equations, it has been developed by automating the process of data input, estimation and running the model so that the level of difficulty in maintaining the consistency of the relationships between variables in the model is low.

The Determinant of Core Inflation in Indonesia.

Abstract:

This paper analyzes the factors that influence core inflation in Indonesia using the OLS model and quarterly data (qtoq), we argue that in the period after the 1997/1998 economic crisis, core inflation was influenced by past (backward-looking) core inflation. inflation expectations (consensus forecast), output gap, exchange rate (change and level of volatility), and M1 growth. Compared to the whole sample (1992-2011), in the period after the economic crisis the role of the output gap became significant, the exchange rate pass through was reduced, and the role of exchange rate volatility became larger. Using the output gap MV filter, it was found that there was a threshold output gap after a period of crisis.

Meanwhile, the role of the policy rate (BI rate) in reducing core inflation is relatively limited. Using the ARDL model and monthly data (yoy) from January 2002 to June 2011, we argue that the movement of administered price inflation and volatile food inflation affects the movement of core inflation in Indonesia. In general, the impact of increases in volatile foods is greater than the impact of increases in administered prices on core inflation. Several administered price commodities that have a significant impact on core inflation are gasoline, urban transportation, household fuel, and telephone tariffs. Meanwhile, several volatile foods commodities that had a significant impact on core inflation were rice, beef, milk, noodles, and cooking oil.

Chapters

Strategy for Economic Transformation. In 2019 Economic Report on Indonesia. Bank Indonesia. March 2020.

Awards

Bank Indonesia scholarship 2015-2016, 2021-2024. Master and PhD program.

Bank Indonesia scholarship for undergraduate program for academic achievement, 2006.

Honorable Mention on Mathematical Contest in Modeling (MCM) as Delegation from Indonesia, by the Consortium for Mathematics and Its Applications (COMAP), 2006.

Dean's List, by the Faculty of Mathematics and Natural Science ITB, 2006.

Skills

Programming language and software: Python, MATLAB, SPSS, EViews, STATA, SAS.

Research Methods: Time-series econometrics (i.e., ARMA, VAR, SVAR, ARDL), panel regression, simultaneous regression and system simulation, dynamic stochastic general equilibrium (DSGE).

Languages

Indonesia (Native)

English (Professional)
